Algorithms and Data Structures (BADS)

Exam 31 May 2012

Thore Husfeldt, ITU

Instructions

What to bring. You can bring any written aid you want. This includes the course book and a dictionary. In fact, these two things are the only aids that make sense, so I recommend you bring them and only them. But if you want to bring other books, notes, print-out of code, old exams, or today's newspaper you can do so. (It won't help.)

You can't bring electronic aids (such as a laptop) or communication devices (such as a mobile phone). If you really want, you can bring an old-fashioned pocket calculator (not one that solves recurrence relations), but I can't see how that would be of any use to you.

Answering multiple-choice questions. In the multiple-choice questions, there is one and only one correct answer. However, to demonstrate partial knowledge, you are allowed to check 2 or more boxes, but this earns you less than full points for that question.

| number of checked boxes | 0 | 1 | 2 | 3 | 4 |
|--------------------------------------|---|-------|------|-------|---|
| points if correct answer checked | | 1 | 0.5 | • | 0 |
| points if correct answer not checked | 0 | -0.33 | -0.5 | -0.62 | |

In particular, the best thing is to only check the correct answer, and the worst thing is to check all answers but the correct one. If you don't check anything (or check *all* boxes) your score is 0. Also, if you check boxes at random, your expected score is 0. Some questions are worth more points, or allow more than four choices; their points are scaled accordingly. For more details, read [Gudmund Skovbjerg Frandsen, Michael I. Schwartzbach: A singular choice for multiple choice. SIGCSE Bulletin 38(4): 34–38 (2006)].

(Just to make sure: a question that is not multiple-choice cannot give you negative points.)

Typographic remark. I follow the typographic convention used implicity in the course book that a one-letter Java variable, such as N, is typeset in italics like a mathematical variable in body text: *N*.

| 2. Class Y. The next few questions all co | oncern the class defined in fig. 1. |
|--|---|
| (a) (1 pt.) Class Y behaves like which | well-known data structure? |
| A Stack. | B Queue. |
| C Priority queue. | D Union–Find. |
| (b) (1 <i>pt.</i>) Write the body of a meth structure. | od int size() that returns the number of elements in the data |
| A return N; | B return A.length; |
| <pre>C return A[N];</pre> | □ return hi - lo; |
| (c) (1 pt.) Which invariant does the da | ata structure maintain after every public operation? |
| $oxed{A}$ N < A.length $oxed{\mathbb{C}}$ hi < N | B lo < hi D hi == N |
| (d) (1 pt.) Draw the data structure (in following operations: | ncluding the contents of A and the values hi, lo, and N) after the |
| <pre>Y y = new Y(); y.insert(1); y.remove(); y.insert(2); y.remove(); y.insert(3);</pre> | |
| | your drawing goes in the shaded region |
| | loes a single call to Y. remove take in the worst case? (To make this compiler performs no clever optimisations. That is, every array vill actually be performed.) B 2. D 7. |
| (f) (1 pt.) How many array accesses of | does a single call to the most expensive public method of Y take in |
| the worst case? $\boxed{\mathbb{A}} \sim 4N.$ | B 2. |
| $\mathbb{C}\sim 2N$. | D 7. |
| | mber of array accesses per operation in a sequence of k Y.insert |
| \triangle linear in k . | B constant. |
| \square linearithmic in k . | \square quadratic in k . |
| | · |
| B constant in the worst case. | |
| | k, but linear in k in the worst case. |
| \square quadratic in k in the worst case | |
| • | |
| | acture Y uses space linear in N. Explain your answer on a separate short as you can, but not shorter. If you use more than half a page of abstraction.) |

```
public class Y<Key extends Comparable<Key>>
 private Key[] A = (Key[]) new Comparable[1];
 private int lo, hi, N;
 public void insert(Key in)
   A[hi] = in;
   hi = hi + 1;
   if (hi == A.length) hi = 0;
   N = N + 1;
   if (N == A.length) rebuild();
 }
 public Key remove() // assumes Y is not empty
   Key out = A[lo];
   A[lo] = null;
   lo = lo + 1;
   if (lo == A.length) lo = 0;
   N = N - 1;
   return out;
 }
 private void rebuild()
   Key[] tmp = (Key[]) new Comparable[2*A.length];
   for (int i = 0; i < N; i++)
   tmp[i] = A[(i + lo) % A.length];
   A = tmp;
   lo = 0;
   hi = N;
}
```

Figure 1: Class Y.

3. Operation of common algorithms and data structures.

(a) (1 pt.) Consider the following sequence of operations on a symbol table:

put(2,5) put(3,1) get(2) get(3) put(2,10) get(2)

What sequence of values is returned by the get-operations? (Your answer goes into the shaded box:)

| (b) (| 1 pt.) I have sorted the word "how much wood would a woodchuck chuck if a woodchuck would |
|-------|---|
| C | thuck wood?" using MSD string sort ([SW, section 5.1]). In the figure below, mark all characters that |
| 7 | vere examined by the MSD string sort with a circle. |

a
a
chuck
chuck
how
if
much
wood
woodchuck
woodchuck
would
would

(c) (1 pt.) Draw the 2-3 tree that results when you insert the keys M Y Q U E S T I O N in that order into an initially empty tree. (Your answer goes into the shaded box:)

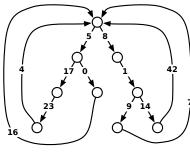

In the following 7 questions, consider the sequence of integers, 6425 5467 4857 5479 4794 2386 5678 9974

as input to a sorting algorithm. Each question describes an intermediate stage of one and only one sorting algorithm: quicksort, (top-down) merge sort, insertion sort, selection sort, LSD string sort, MSD string sort, and heap sort. (Every algorithm corresponds to exactly one sequence.) Which is which?

| (α) $(\frac{\pi}{2}$ $pi.)$ 3078 | 5467 4857 | 7 5479 4794 | 2386 6425 9974 | | |
|---|--|--|---|---------|--------|
| A quick | B merge | Cinsert | D select E LSD | F MSD | G heap |
| (e) $(\frac{1}{2} pt.)$ 9974 | 6425 5678 | 3 5479 4794 | 2386 4857 5467 | | |
| A quick | B merge | Cinsert | D select E LSD | F MSD | G heap |
| (f) $(\frac{1}{2} pt.)$ 4857 | 5467 5479 | 6425 2386 | 4794 5678 9974 | | |

/

4. Design of algorithms. A *looped tree* is a weighted, directed graph built from a binary tree by adding an edge from every leaf back to the root. Every edge has a non-negative weight.

A looped tree.

- (a) (0 *pt.*) Convince yourself that the shortest path from the leftmost leaf to the rightmost leaf in the above example graph has length 27.
- (b) (1 *pt.*) Given such a graph and two vertices, *u* and *v*, we want to find the shortest path from *u* to *v*. Clearly Dijkstra's algorithm ([SW, Algorithm 4.9]) solves this problem. What is the running time in terms of *N*, the number of nodes?
- (c) (5 pt.) Design a faster algorithm for this problem. If you want, you can make use of existing algorithms, models, or data structures from the book, please be precise in your references (for example). Estimate the running time of your construction. Be short and precise. This question can be perfectly answered on half a page of text, maybe less. If you find yourself writing more than one page, you're using the wrong level of detail.
